These transcription factors contain the homeobox protein-binding DNA motif, also found in other toolkit genes, and create the basic pattern of the body along its front-to-back axis. These genes are reused, unchanged, many times in different parts of the embryo and at different stages of development, forming a complex cascade of control,

switching other regulatory genes as well as structural genes on and off in a precise pattern. A strong positive response was detected in the mucosal cells of the skin, gills and gut, indicating a role in the mucosal immune defence at these sites.

Biologists including Ernst Mayr had believed that eyes had arisen in the animal kingdom. They now propose looking to evolutionary developmental biology (EvoDevo) to overcome the distinction and integrate the proximate and ultimate causal frameworks.
